

## Chemistry BC2001x: General Chemistry I

Lecture 16: Tuesday November 10, 2009

Topics: Diprotic acid titrations; distribution diagrams

Pick up

(1) Acid-base distribution diagrams

This topic is **not** covered in Chang.

(2) Graded Problem Set 7

1

## Titration of a weak acid with strong base

Review from last lecture:

Adding base so pH rises throughout

at  $V_e = 40.0$  mL: very steep change

Buffer region: 10% to 90% of  $V_e$ :  
pH rises slowly.

Halfway to equivalence,  $\text{pH} = \text{p}K_a$

Equivalence point has  $\text{pH} > 7$ :  
weak acid HA has been converted to  
conjugate weak base  $A^-$ .

(When the acid is quite weak, there  
is a small steeper rise in pH at the  
very beginning.)

2

## Comparison of strong/weak titration curves

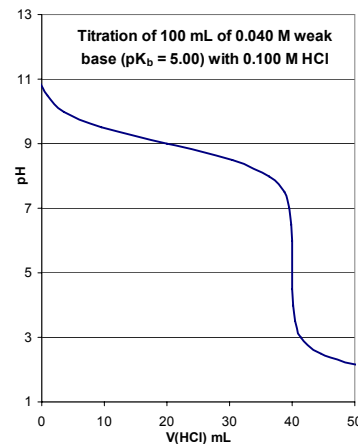

Both have **very steep** jump at  $V_e$ . pH at  $V_e$  differs ( $> 7$  for weak).

Identical after  $V_e$ .

Before  $V_e$ : weak acid has larger pH throughout, somewhat steeper rise  
in buffer region. Sometimes a brief steeper climb at the beginning.

3

## Titration of a weak base with strong acid

Adding acid: pH falls throughout

at  $V_e = 40.0$  mL: steep change

Halfway to equivalence,  $\text{pH} = \text{p}K_a$

( $\text{p}K_b = 5$  so  $\text{p}K_a = 14 - 5 = 9$ )

Equivalence point has  $\text{pH} < 7$ :  
weak base B has been converted  
to conjugate weak acid  $HB^+$ .

Calculations very similar to those  
for weak acid; see problem set 8.

4

## Distribution diagrams: monoprotic acid

Let  $f_B$  = fraction in basic form ( $A^-$ )  
and  $f_A$  = fraction in acidic form (HA)

$$f_B = \frac{[A^-]}{[A^-] + [HA]}$$

$$1/f_B = \frac{[A^-] + [HA]}{[A^-]} = 1 + \frac{[HA]}{[A^-]}$$

$$K_a = \frac{[H^+][A^-]}{[HA]} \rightarrow \frac{[HA]}{[A^-]} = \frac{[H^+]}{K_a}$$

$$1/f_B = 1 + \frac{[H^+]}{K_a} = \frac{K_a + [H^+]}{K_a}$$

$$f_B = \frac{K_a}{K_a + [H^+]}$$

$$f_A = (1 - f_B) = \frac{[H^+]}{K_a + [H^+]}$$

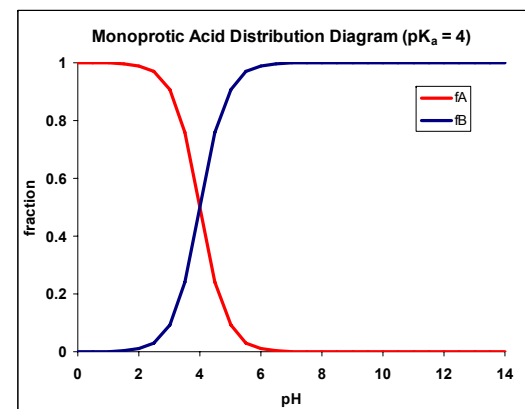

For a given  $K_a$ , we will plot  $f_A$  and  $f_B$  vs. pH

*(Do not memorize these equations!)*

(Observe: only pH and  $K_a$ , not concentration of the weak acid or base, enter into calculations of  $f$ 's!)

5

## Distribution diagrams: monoprotic acid

The shapes are the same for all weak acids;  
the curves simply shift left/right so they cross at  $\text{pH} = \text{p}K_a$

6

## Diprotic acid titration: qualitative facts

### CASE I:

Big difference in  $K_a$ 's:

$$\text{p}K_{a1} = 4.00 \text{ and } \text{p}K_{a2} = 8.00$$

$$K_{a1}/K_{a2} = 10^4 = 10,000$$

pH rises steeply  
both at  $V_{1e}$  (20 mL)  
and  $V_{2e}$  (40 mL)

looks like sequential  
monoprotic titration curves

Halfway to  $V_{1e}$   $\text{pH} = \text{p}K_{a1}$

Halfway between  
 $V_{1e}$  and  $V_{2e}$ ,  $\text{pH} = \text{p}K_{a2}$

7

## Diprotic acid titrations

### CASE II: less difference

$$\text{p}K_{a1} = 6.00 \text{ and } \text{p}K_{a2} = 8.00$$

$$K_{a1}/K_{a2} = 100$$

pH rises steeply at  $V_{2e}$   
but **not** at  $V_{1e}$

The two stages of hydrolysis  
are **overlapping**:

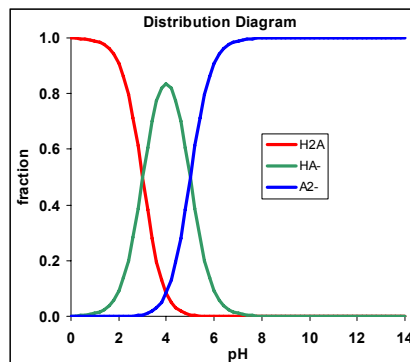

8

## Distribution diagrams: diprotic acids

$pK_{a1} = 3$  and  $pK_{a2} = 10$

$pK_{a1} = 3$  and  $pK_{a2} = 5$

9

## Distribution diagram: triprotic acid $H_3PO_4$

pH	dominant form
< 2.1	$H_3PO_4$
2.1 - 7.2	$H_2PO_4^-$
7.2 - 12.5	$HPO_4^{2-}$
> 12.4	$PO_4^{3-}$

In commonly used "phosphate buffers" with pH around 7, the two important species are  $H_2PO_4^-$  and  $HPO_4^{2-}$ , whose ratio is governed by  $K_{a2}$ .  $[H_3PO_4]$  and  $[PO_4^{3-}]$  are negligible, so  $K_{a1}$  and  $K_{a3}$  have no effect on the pH.

10

## Distribution diagram: triprotic acid $H_3PO_4$

logarithmic version  
(look at y-axis)  
(to see smaller values):

at pH = 6:

most is  $H_2PO_4^-$   
between 1 & 10%  $HPO_4^{2-}$   
about 0.01%  $H_3PO_4$   
 $10^{-6}$  %  $PO_4^{3-}$

11

## Distribution diagrams

Not used for calculations, but show clearly how and why we can make useful approximations with acid/base solutions.

Simply by considering the  $pK_a$ 's of the acid, and the pH of the solution, we can say which species are present in large amount, and which are negligible.

For weak monoprotic acid, if pH is 2 units less than  $pK_a$  or less, 99+% will be in form HA, less than 1%  $A^-$ .

For a diprotic acid, if  $pH \ll pK_{a2}$ , to find pH or  $H^+$ , we can ignore  $A^{2-}$ , and focus only on the species involved in  $K_{a1}$ ,  $H_2A$  and  $HA^-$ .

For a diprotic acid, if  $pH \gg pK_{a1}$ , to find pH or  $H^+$ , we can ignore  $H_2A$ , and focus only on the species involved in  $K_{a2}$ ,  $HA^-$  and  $A^{2-}$ .

For phosphoric acid with pH between about 4 and 10, both  $H_3PO_4$  and  $PO_4^{3-}$  are negligible. The pH can be found considering  $H_2PO_4^-$  and  $HPO_4^{2-}$  only, and the K between them:  $K_{a2}$ .
